## 1.1.4 Function Documentation

### 1.1.4.1 int Mat\_CalcSingleSubscript ( int *rank*, int \* *dims*, int \* *subs* )

Calculates a single linear subscript (0-relative) given a 1-relative subscript for each dimension. The calculation uses the formula below where index is the linear index, s is an array of length RANK where each element is the subscript for the correspondind dimension, D is an array whose elements are the dimensions of the variable.

$$index = \sum_{k=0}^{RANK-1} [(s_k - 1) \prod_{l=0}^k D_l]$$

#### Parameters

<i>rank</i>	Rank of the variable
<i>dims</i>	dimensions of the variable
<i>subs</i>	Dimension subscripts

**Returns**

Single (linear) subscript

**1.1.4.2 int\* Mat\_CalcSubscripts ( int rank, int \* dims, int index )**

Calculates 1-relative subscripts for each dimension given a 0-relative linear index. Subscripts are calculated as follows where s is the array of dimension subscripts, D is the array of dimensions, and index is the linear index.

$$s_k = \lfloor \frac{1}{L} \prod_{l=0}^k D_l \rfloor + 1$$

$$L = index - \sum_{l=k}^{RANK-1} s_k \prod_{m=0}^k D_m$$

**Parameters**

<i>dims</i>	dimensions of the variable
<i>index</i>	linear index

**1.1.4.10 matvar\_t\* Mat\_VarCreate ( const char \* *name*, int *class\_type*, int *data\_type*, int *rank*, int \* *dims*, void \* *data*, int *opt* )**

Creates a MAT variable that can be written to a Matlab MAT file with the given name, data type, dimensions and data. Rank should always be 2 or more. i.e. Scalar values would have rank=2 and dims[2] = {1,1}. Data type is one of the MAT\_T types. MAT adds MAT\_T\_STRUCT and MAT\_T\_CELL to create Structures and Cell Arrays respectively. For MAT\_T\_STRUCT, data should be a NULL terminated array of [matvar\\_t](#) \* variables (i.e. for a 3x2 structure with 10 fields, there should be 61 [matvar\\_t](#) \* variables where the last one is NULL). For cell arrays, the NULL termination isn't necessary. So to create a cell array of size 3x2, data would be the address of an array of 6 [matvar\\_t](#) \* variables.

EXAMPLE: To create a struct of size 3x2 with 3 fields:

```
int rank=2, dims[2] = {3,2}, nfields = 3;
matvar_t **vars;

vars = malloc((3*2*nfields+1)*sizeof(matvar_t *));
vars[0] = Mat_VarCreate(...);
:
vars[3*2*nfields-1] = Mat_VarCreate(...);
vars[3*2*nfields] = NULL;
```

EXAMPLE: To create a cell array of size 3x2:

```
int rank=2, dims[2] = {3,2};
matvar_t **vars;

vars = malloc(3*2*sizeof(matvar_t *));
vars[0] = Mat_VarCreate(...);
:
vars[5] = Mat_VarCreate(...);
```

## Parameters

<i>name</i>	Name of the variable to create
<i>class_type</i>	class type of the variable in Matlab(one of the mx Classes)
<i>data_type</i>	data type of the variable (one of the MAT_T_ Types)
<i>rank</i>	Rank of the variable
<i>dims</i>	array of dimensions of the variable of size rank
<i>data</i>	pointer to the data
<i>opt</i>	0, or bitwise or of the following options: <ul style="list-style-type: none"> <li>• MEM_CONSERVE to just use the pointer to the data and not copy the data itself. Note that the pointer should not be freed until you are done with the mat variable. The Mat_VarFree function will NOT free data that was created with MEM_CO-NSERVE, so free it yourself.</li> <li>• MAT_F_COMPLEX to specify that the data is complex. The data variable should be a contigouse piece of memory with the real part written first and the imaginary second</li> <li>• MAT_F_GLOBAL to assign the variable as a global variable</li> <li>• MAT_F_LOGICAL to specify that it is a logical variable</li> </ul>

If `copy_fields` is non-zero, the indexed structures are copied and should be freed, but if `copy_fields` is zero, the indexed structures are pointers to the original, but should still be freed since the `mem_conserve` flag is set so that the structures are not freed. MAT File version must be 5.

## Parameters

<code>stride</code>	vector of length rank with strides for each diemnsion.
