1 PostScript functions SetMatrixThreeD, ProjThreeD, and SetMatrixEmbed

The viewpoint for 3D coordinates is given by three angles: α , β and γ . α and β determine the direction from which one is looking. γ then determines the orientation of the observing.

When α , β and γ are all zero, the observer is looking from the negative part of the y -axis, and sees the xz -plane the way in 2D one sees the xy plan. Hence, to convert the 3D coordinates to their 2D project, $\langle x, y, z \rangle$ map to $\langle x, z \rangle$.

When the orientation is different, we rotate the coordinates, and then perform the same projection.

We move up to latitude β , over to longitude α , and then rotate by γ . This means that we first rotate around y -axis by γ , then around x -axis by β , and the around z -axis by α .

Here are the matrices:

$$\begin{aligned} R_z(\alpha) &= \begin{bmatrix} \cos \alpha & -\sin \alpha & 0 \\ \sin \alpha & \cos \alpha & 0 \\ 0 & 0 & 1 \end{bmatrix} \\ R_x(\beta) &= \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos \beta & \sin \beta \\ 0 & -\sin \beta & \cos \beta \end{bmatrix} \\ R_y(\gamma) &= \begin{bmatrix} \cos \gamma & 0 & -\sin \gamma \\ 0 & 1 & 0 \\ \sin \gamma & 0 & \cos \gamma \end{bmatrix} \end{aligned}$$

The rotation of a coordinate is then performed by the matrix $R_z(\alpha)R_x(\beta)R_y(\gamma)$. The first and third columns of the matrix are the basis vectors of the plan upon which the 3D coordinates are project (the old basis vectors were $\langle 1, 0, 0 \rangle$ and $\langle 0, 0, 1 \rangle$; rotating these gives the first and third columns of the matrix).

These new basis vectors are:

$$\begin{aligned} \tilde{x} &= \begin{bmatrix} \cos \alpha \cos \gamma - \sin \beta \sin \alpha \sin \gamma \\ \sin \alpha \cos \gamma + \sin \beta \cos \alpha \sin \gamma \\ \cos \beta \sin \gamma \end{bmatrix} \\ \tilde{z} &= \begin{bmatrix} -\cos \alpha \sin \gamma - \sin \beta \sin \alpha \cos \gamma \\ -\sin \alpha \sin \gamma + \sin \beta \cos \alpha \cos \gamma \\ \cos \beta \cos \gamma \end{bmatrix} \end{aligned}$$

Rather than specifying the angles α and β , the user gives a vector indicating where the viewpoint is. This new viewpoint is the rotation o the old viewpoint. The old viewpoint is $\langle 0, -1, 0 \rangle$, and so the new viewpoint is

$$R_z(\alpha)R_x(\beta) \begin{bmatrix} 0 \\ -1 \\ 0 \end{bmatrix} = \begin{bmatrix} \cos \beta \sin \alpha \\ -\cos \beta \cos \alpha \\ \sin \beta \end{bmatrix} = \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix}$$

Therefore,

$$\begin{aligned}\alpha &= \arctan(v_1/v_2) \\ \beta &= \arctan(v_3 \sin \alpha / v_1)\end{aligned}$$

Unless $p_1 = p_2 = 0$, in which case $\alpha = 0$ and $\beta = \text{sign}(p_3)90$, or $p_1 = p_3 = 0$, in which case $\beta = 0$.

The syntax of `SetMatrixThreeD` is $v_1\ v_2\ v_3\ \gamma$. `SetMatrixThreeD` first computes

$$\begin{aligned}a &= \sin \alpha & b &= \cos \alpha \\ c &= \sin \beta & d &= \cos \beta \\ e &= \sin \gamma & f &= \cos \gamma\end{aligned}$$

and then sets `Matrix3D` to $[\tilde{x}\ \tilde{z}]$.

```

The syntax of `ProjThreeD` is $x\ y\ z$ `ProjThreeD` $x'\ y'$ where $x' = \langle x, y, z \rangle \cdot \tilde{x}$ and $y' = \langle x, y, z \rangle \cdot \tilde{z}$.

```

1 /ProjThreeD {

```

To embed 2D $\langle x, y \rangle$ coordinates in 3D, the user specifies the normal vector and an angle. If we decompose this normal vector into an angle, as when converting 3D coordinates to 2D coordinates, and let $\hat{\alpha}$, $\hat{\beta}$ and $\hat{\gamma}$ be the three angles, then when these angles are all zero the coordinate $\langle x, y \rangle$ gets mapped to $\langle x, 0, y \rangle$, and otherwise $\langle x, y \rangle$ gets mapped to

$$R_z(\hat{\alpha})R_x(\hat{\beta})R_y(\hat{\gamma}) \begin{bmatrix} x \\ 0 \\ y \end{bmatrix} = \begin{bmatrix} \hat{x}_1x + \hat{z}_1y \\ \hat{x}_2x + \hat{z}_2y \\ \hat{x}_3x + \hat{z}_3y \end{bmatrix}$$

where \hat{x} and \hat{z} are the first and third columns of $R_z(\hat{\alpha})R_x(\hat{\beta})R_y(\hat{\gamma})$.

Now add on a 3D-origin:

$$\begin{bmatrix} \hat{x}_1x + \hat{z}_1y + x_0 \\ \hat{x}_2x + \hat{z}_2y + y_0 \\ \hat{x}_3x + \hat{z}_3y + z_0 \end{bmatrix}$$

Now when we project back onto 2D coordinates, we get

$$\begin{aligned} x' &= \tilde{x}_1(\hat{x}_1x + \hat{z}_1y + x_0) + \tilde{x}_2(\hat{x}_2x + \hat{z}_2y + y_0) + \tilde{x}_3(\hat{x}_3x + \hat{z}_3y + z_0) \\ &= (\tilde{x}_1\hat{x}_1 + \tilde{x}_2\hat{x}_2 + \tilde{x}_3\hat{x}_3)x \\ &+ (\tilde{x}_1\hat{z}_1 + \tilde{x}_2\hat{z}_2 + \tilde{x}_3\hat{z}_3)y \\ + \tilde{x}_1x_0 + \tilde{x}_2y_0 + \tilde{x}_3z_0y' &= \tilde{z}_1(\hat{x}_1x + \hat{z}_1y + x_0) + \tilde{z}_2(\hat{x}_2x + \hat{z}_2y + y_0) + \tilde{z}_3(\hat{x}_3x + \hat{z}_3y + z_0) \\ &= (\tilde{z}_1\hat{x}_1 + \tilde{z}_2\hat{x}_2 + \tilde{z}_3\hat{x}_3)x \\ &+ (\tilde{z}_1\hat{z}_1 + \tilde{z}_2\hat{z}_2 + \tilde{z}_3\hat{z}_3)y \\ &+ \tilde{z}_1x_0 + \tilde{z}_2y_0 + \tilde{z}_3z_0 \end{aligned}$$

Hence, the transformation matrix is:

$$\begin{bmatrix} \tilde{x}_1\hat{x}_1 + \tilde{x}_2\hat{x}_2 + \tilde{x}_3\hat{x}_3 \\ \tilde{z}_1\hat{x}_1 + \tilde{z}_2\hat{x}_2 + \tilde{z}_3\hat{x}_3 \\ \tilde{x}_1\hat{z}_1 + \tilde{x}_2\hat{z}_2 + \tilde{x}_3\hat{z}_3 \\ \tilde{z}_1\hat{z}_1 + \tilde{z}_2\hat{z}_2 + \tilde{z}_3\hat{z}_3 \\ \tilde{x}_1x_0 + \tilde{x}_2y_0 + \tilde{x}_3z_0 \\ \tilde{z}_1x_0 + \tilde{z}_2y_0 + \tilde{z}_3z_0 \end{bmatrix}$$

The syntax of `SetMatrixEmbed` is $x_0\ y_0\ z_0\ v_1\ v_2\ v_3\ \gamma$ `SetMatrixEmbed`

`SetMatrixEmbed` first sets $\langle x_1\ x_2\ x_3\ y_1\ y_2\ y_3 \rangle$ to the basis vectors for the viewpoint projection (the tilde stuff above). Then it sets `Matrix3D` to the basis vectors for the embedded plane. Finally, it sets the transformation matrix to the matrix given above.

5 Arithmetic

\pst@divide This is adapted from Donald Arseneau's `shapepar.sty`. Syntax:

```

\pst@divide{<numerator>}{<denominator>}{{<command>}}
\pst@divide{<numerator>}{<denominator>}

```

<numerator> and <denominator> should be dimensions. \pst@divide sets <command> to <num>/<den> (in points). \pst@@divide sets \pst@dimg to <num>/<den>.

```

1 \def\pst@divide#1#2#3{%
2   \pst@divide{#1}{#2}%
3   \pst@dimtonum\pst@dimg{#3}%
4 \def\pst@divide#1#2{%
5   \pst@dimg=#1\relax
6   \pst@dimh=#2\relax
7   \pst@cntg=\pst@dimh
8   \pst@cnth=67108863
9   \pst@@divide\pst@@divide\pst@@divide\pst@@divide
10  \divide\pst@dimg\pst@cntg}

```

The number 16 is the level of uncertainty. Use a lower power of 2 for more accuracy (2 is most precise). But if you change it, you must change the repetitions of \pst@@divide in \pst@divide above:

$$\text{precision}^{\text{repetitions}} = 65536$$

(E.g., $16^4 = 65536$).

```

1 \def\pst@@divide{%
2   \ifnum

```

```

3   \ifnum\pst@dim<\z@-\fi\pst@dim<\pst@cnth
4   \multiply\pst@dim\sixt@n
5 \else
6   \divide\pst@cnth\sixt@n
7 \fi}

```

\pst@pyth Syntax:

```
\pst@pyth{<dim1>}{<dim2>}{<dimen register>}
```

<dimen register> is set to $((dim1)^2 + (dim2)^2)^{1/2}$.

The algorithm is copied from PiCTeX, by Michael Wichura (with permission). Here is his description:

Suppose $x > 0$, $y > 0$. Put $s = x + y$. Let $z = (x^2 + y^2)^{1/2}$. Then $z = s \times f$, where

$$f = (t^2 + (1 - t)^2)^{1/2} = ((1 + \tau^2)/2)^{1/2}$$

and $t = x/s$ and $\tau = 2(t - 1/2)$.

```

1 \def\pst@pyth#1#2#3{%
2   \begingroup

```

\pst@sinandcos Syntax:

```
\pst@sinandcos{<dim>}{<int>}
```

<dim>, in sp units, should equal 100,000 times the angle, in degrees between 0 and 90. <int> should equal the angle's quadrant (0, 1, 2 or 3). \pst@dimg is set to $\sin(\theta)$ and \pst@dimh is set to $\cos(\theta)$ (in pt's).

The algorithms uses the usual McLaurin expansion.

```

7 Affin Transformations

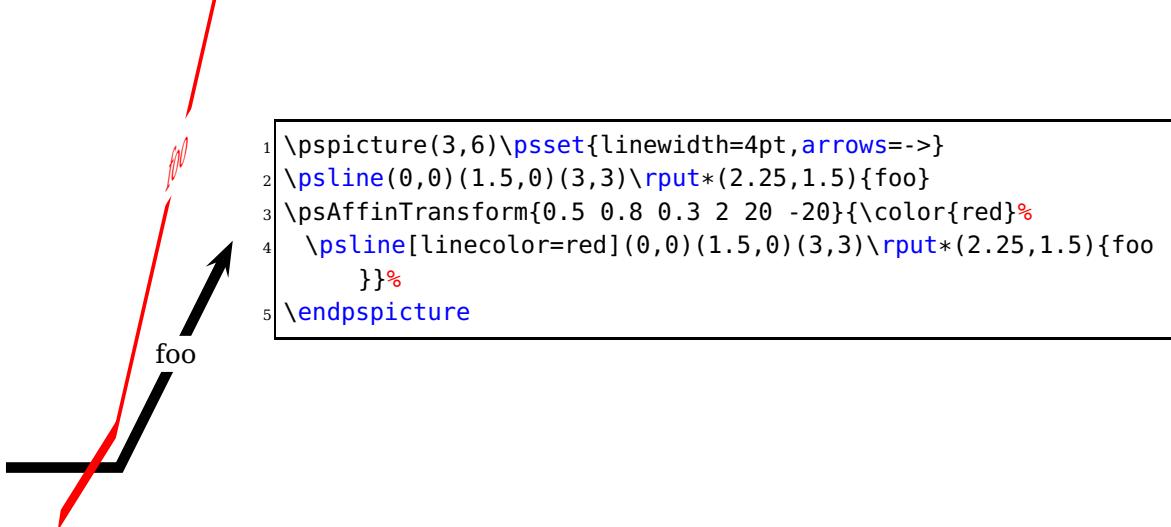

```
\psAffinTransform [Options] {transformation matrix}{object}
```

The transformation matrix must be a list of 6 values divided by a space. For a translation modify the last two values of $1001dxdy$. The values for dx and dy must be of the unit pt! For a rotation we have the transformation matrix

$$\begin{bmatrix} \cos(\alpha) \sin(\alpha) & 0 \\ -\sin(\alpha) \cos(\alpha) & 0 \\ 0 & 1 \end{bmatrix} \quad (1)$$

For `\psAffinTransform` the four values have to be modified a cos a sin a sin neg a cos 0 0. Tilting can be done with `sx00sy00`. All effects can be combined.

8 List of all optional arguments for `pst-3d`

Key	Type	Default
<code>viewpoint</code>	ordinary	<code>1 -1 1</code>
<code>viewangle</code>	ordinary	<code>0</code>
<code>normal</code>	ordinary	<code>0 0 1</code>
<code>embedangle</code>	ordinary	<code>0</code>
<code>Tshadowsize</code>	ordinary	<code>1</code>
<code>Tshadowangle</code>	ordinary	<code>60</code>
<code>Tshadowcolor</code>	ordinary	<code>lightgray</code>
